<b>Title</b>	Modal identification of output-only systems using frequency domain decomposition
Background	
<b>Why this paper? How'd you find it?</b>	I'd like to understand frequency domain decomposition (FDD) since it's such a popular and user-friendly technique
<b>Study Objective</b>	How does the use of FDD help determine dynamic properties of structure from output-only vibration measurements due to ambient/white noise excitation?
<b>Intended gaps to fill</b>	Peak picking from FFT of signals is user-friendly but can miss close-frequency modes.
<b>Authors</b>	Rune Brincker, Lingmi Zhang, Palle Andersen
<b>Affiliations</b>	Aalborg University, Denmark, Nanjing University, China, Structural Vibration Solutions ApS, Denmark
<b>Funding Source</b>	Probably the universities and structural vibration solutions
<b>Journal / Field</b>	Smart Materials & Structures
<b>Date</b>	2001
<b>Historical Context</b>	Gauss DTFT 1805, Cooley-Tukey FFT 1965
<b>Relationship to SEMM</b>	Modal identification
Methods	
<b>Given:</b>	Ambient Vibration
<b>Find:</b>	Modal frequencies, shapes, damping ratios
<b>Experimental Design</b>	Apply FDD to mathematical model's simulated outputs with no, 10%, and 20% noise. From PSD, obtain mode shapes and frequencies. Use IFFT to reconstruct SDOF autocorrelation histories. From autocorrelation histories, obtain damping ratios.
<b>Test Subjects</b>	Mathematical 2 storey frame model
Results	
<b>Baseline for comparison</b>	True dynamic properties of mathematical model
<b>Metric for comparison</b>	Difference between true and estimated dynamic properties
<b>Difference from baseline</b>	Very close
Conclusions	
<b>Authors'</b>	FDD good for identifying close modes and deals well with noise
<b>Yours</b>	Not sure what they mean by "Higher bias for less dominant modes". Would like to see application to a real physical structure, especially for damping of a non-steel structure
<b>Applications</b>	SHM
